

AMENDMENTS TO THE CLAIMS

1-11 (Canceled)

12. (Currently amended) A sub-assembly comprising an electronic module, said module containing a generally planar surface defined by ~~4~~ ^{--four--} sides, and an interposer containing a rectangular housing for controlling the sliding motion of said module relative to said interposer, said housing having two contiguous edges containing restraints positioned to contact two sides of the module and springs connecting the other two contiguous edges of the interposer to the other two sides to the module, said surface having small irregularities that contribute to a lack of planarity, the module clamped to said interposer, said interposer including two stops spacedly positioned at right angles to the planar surface of the interposer and along two edges thereof, and projecting toward said module, such that the combined height of the stops is at least equal to the maximum expected rocking movement of the planar surface due to the irregularities, whereby the stops engage the generally planar surface of the module

13. (Canceled)

14. (Canceled)

15. (Currently amended) The sub-assembly according to claim 12 ~~14~~ wherein the planar surface of the module contains a plurality of contact sites that are

aligned by the interposer member with corresponding contact pads on a printed circuit board during subsequent assembly.

16. (Original) An electronic module adapted to be electrically interconnected to a printed circuit board, through one or more contact sites on a surface of said electronic module with contact pads on a surface of the printed circuit board, said module containing a convex surface, an interposer between said printed circuit board and the convex surface of said module, said interposer including a compressible electrically conductive spring element for each contact pad and its corresponding contact site, and further including two spacedly positioned stops projecting from the interposer toward said module, such that the combined height of the stops is at least equal to the maximum expected curvature of the convex surface, whereby the stops engage the perimeter of the module.

17. (Original) The electronic module according to claim 16 wherein two stops extend at right angles to the planar surface of the interposer and along two edges thereof, into contact with the module.

18. (Original) The electronic module according to claim 16 further wherein the interposer contains means for controlling the sliding motion of said module relative to said interposer, said means comprising a rectangular housing having two contiguous edges containing restraints positioned to align the contact sites of the module

with the contact pads of the printed circuit board, and springs connecting the other two contiguous edges of the interposer to the other two edges to the module.
